LIST OF EXPERIMENTSPAGE NO.
Introduction to chemistry laboratory- Molarity, Normality ,Primary, Secondary Standard Solutions, Volumetric titrations, Quantitative analysis etc. ..... 05

1. Determination of HCl using standard $\mathrm{Na}_{2} \mathrm{CO}_{3}$ solution. ..... 11
2. Determination of Alkalinity of a sample containing $\mathrm{Na}_{2} \mathrm{CO}_{3}$ and NaOH ..... 13
3. Determination of Mn (II) using standard Oxalic acid solution. ..... 15
4. Determination of Ferrous iron using standard $\mathrm{K}_{2} \mathrm{Cr}_{2} \mathrm{O}_{7}$ ..... 17
5. Determination of copper(II) using standard Hypo solution ..... 19
6. Determination of temporary and permanent hardness of water using standard EDTA solution. ..... 21
7. Determination of Iron (III) by a calorimetric method . ..... 25
8. Determination of the concentration of acetic acid using Sodium hydroxide byPH metry method ..... 27
9.Derermination of Iso electric point of Amino acids using Ph metric method/ Conductometric method ..... 29
9. Determination of the concentration of strong acid by strong base (by Conductometric method) ..... 33
10. Determination of the concentration of strong acid by strong base (by Potentiometric method) ..... 35
11. Determination of $\mathrm{CaCO}_{3}$ present in an egg shell ..... 37
12. Determination of Vitamin - C ..... 39
13. Preparation of Nylon 6,6 and Bakelite( demonstration only) ..... 40
ADDITONAL EXPERIMENTS BEYOND CURRICULAM
14. Estimation of Chromium (V1) by Idometry ..... 45
15. Estimation of Available chlorine in bleaching powder by Iodometry ..... 47
VIVA VOSE QUESTIONS ..... 48

## INTRODUCTION

The chemical analysis is broadly divided into qualitative and quantitative analysis.
Qualitative analysis deals with the detection and identification of the constituents of substances or constituents present in the given solution.

Quantitative analysis deals with the determination of the amount of the substances present in the given solution.

Quantitative analytical methods can be broadly divided in to three groups.

## 1. Gravimetric Analysis 2. Volumetric Analysis 3. Instrumental Analysis

Any person desirous of analysing a substance by any one of these methods should be acquainted not only with the way of analysis is carried out but also with the techniques and principles involved in these methods. Such knowledge is essential for an engineer with an analytical mind. Hence keeping in view of the importance of the analysis, an introduction to principles and techniques involved in the volumetric analysis are described below.

Volumetric analysis:- Volumetric methods of analysis are generally simple, more rapid, require less apparatus and frequently provide greater accuracy than other analytical methods. Volumetric analysis involves the measurement of volume of the solutions containing the reacting substances.

## Definitions and standard terms

Titration:- The process of finding out the volume of one of the solution required to react completely with a definite volume of other solution.

Titrant:- The solution of known strength generally taken in the burette.
Titrate:-The solution being titrated (whose concentration is to be determined generally taken in the conical flask)

Standard solution:-The solution whose concentration is exactly known.
Primary standard solution:-Solutions whose concentrations do not vary on standing. Generally they are prepared by direct weighing and dissolving known quantity of the solute in definite volume of the solvent. Examples:-Solutions of Oxalic acid, Potassium dichromate etc.

Secondary standard solution:-Solutions whose concentrations can be known by titrating with a primary standard solution. Examples:-Solutions of Sodium hydroxide, Potassium permanganate etc.

Indicator: - Substance used to indicate end point of the titration. The indicator indicates the completion of reaction by change in the colour at the end point.

End point;-The point at which the completion of the titration is judged by a visualColour change
Strength:- Concentration of the solution per unit volume. Strength of the solution can be expressed by the following methods.

Normality;- The number of the gram equivalents of the solute present in one litre of the solution and is represented by N .

Molarity:- Number of the moles of the solute present in one litre of the solution and is represented by M .

Equivalent weight:- Number of parts by weight of it that combines with or displace one part by weight of hydrogen or eight parts by weight of oxygen.

|  | Atomic Weight |
| :---: | :---: |
| Equivalent weight of a metal | = --------------------- |
|  | Valency |
|  | Molecular Weight of an acid |
| Equivalent weight of an acid | = -------------------------------------- |
|  | Basicity of an acid |
|  | Molecular Weight of a base |
| Equivalent weight of a base | ----------------- |
|  | Acidity of a base |

Acidity:- Number of replaceable hydroxide ions of a base
Basicity:- Number of replaceable hydrogen ions of an acid

Volumetric analysis can be classified in to the following four types

1. Neutralization titration
2. Redox Titration
3. Complexometric Titration
4. Precipitation titration

Neutralization titration:

| S.No | Titration | Indicator | Colour change |
| :---: | :---: | :---: | :---: |
| 1. | Strong acid Vs Strong base HCl Vs NaOH | Methyl orange | Orange yellow in basic media Orange red in acidic media |
|  |  | Phenolphthalein | Pink in basic media Colourless in acidic media |
|  | Weak acid Vs Strong base Oxalic acid Vs NaOH | Phenolphthalein | Pink in basic media Colourless in acidic media |
|  | Strong acid Vs Weak base HCl Vs $\mathrm{NH}_{4} \mathrm{OH}$ | Methyl orange | Orange yellow in basic media Orange red in acidic media |

4. Weak acid Vs Weak base

No indicator is suitable

## Redox titrations

| S.No | Titration | Indicator | Colour change |
| :---: | :---: | :---: | :---: |
| 1. | Permanganometry | Self indicator | Colourless to pink |
|  | Oxalic acid Vs $\mathrm{KMnO}_{4}$ | Self indicator | Colourless to pink |
|  | Mohr's Salt Vs $\mathrm{KMnO}_{4}$ | Self indicator | Colourless to pink |
| 2. | Dichrometry | Diphenylamine | Green to Violet |
|  | Mohr's Salt $\mathrm{Vs} \mathrm{K}_{2} \mathrm{Cr}_{2} \mathrm{O}_{7}$ |  |  |

## 3. Idometry

$\mathrm{K}_{2} \mathrm{Cr}_{2} \mathrm{O}_{7}$ Vs Sodium thoisulphate
$\mathrm{CuSO}_{4}$ Vs Sodium thoisulphate
starch starch

Blue to light green

## Equivalent weights of the substances used in volumetric analysis

| S.No | Substance | Chemical formula | Equivalent <br> weight |
| :---: | :---: | :---: | :---: |
| 1 | Sodium Carbonate | $\mathrm{Na}_{2} \mathrm{CO}_{3}$ | 53.06 |
| 2 | Hydrochloric acid | HCl | 36.5 |
| 3 | Sulphuric Acid | $\mathrm{H}_{2} \mathrm{SO}_{4}$ | 49.04 |
| 4 | Oxalic acid | $\mathrm{H}_{2} \mathrm{C}_{2} \mathrm{O}_{4} .2 \mathrm{H}_{2} \mathrm{O}$ | 63.03 |
| 5 | Ferrous Ammonium <br> sulphate(Mohr's salt) | $\mathrm{FeSO}_{4}\left(\mathrm{NH}_{4} \mathrm{SO}_{4}\right)_{2} \mathrm{SO}_{4} \cdot 6 \mathrm{H}_{2} \mathrm{O}$ | 392.14 |
| 6 | Potassium permanganate | $\mathrm{KMnO}_{4}$ |  |
| 7 | Potassium dichromate | $\mathrm{K}_{2} \mathrm{Cr}_{2} \mathrm{O}_{7}$ | 31.06 |
| 8 | Sodium thiosulphate | $\mathrm{Na}_{2} \mathrm{~S}_{2} \mathrm{O}_{3} .5 \mathrm{H}_{2} \mathrm{O}$ | 49.03 |
| 9 | Iron | Fe | 248.19 |
| 10 | Chromium | Cr | 55.85 |
| 11 | Manganeese | Mn | 17.3 |
| 12 | Copper | Cu | 27.5 |

## Complexometric Titrations :

| S.No. | Titration | Indicator | Color Change |
| :--- | :--- | :--- | :--- |
| 1. | Hardness of Water (EDTA) | EBT | Wine red to Blue |
| 2. | Zinc Vs EDTA | EBT | Wine red to Blue |
| 3. | Copper Vs EDTA | Fast Sulphone Black F | Pale blue to bright green |

## Precipitation titrations :

| S.No. | Titration | Indicator | Color Change |
| :--- | :--- | :--- | :--- |
| 1. | Chlorides of water VsAgNO $_{3}$ | Potassium chromate | Yellow to Brick Red |
| 2. | Sodium Chloride VsAgNO | Potassium chromate | Yellow to Brick Red |

Equivalent Weight : The equivalent weight of a substance is defined as that weight of the substance which is chemically equivalent to one gram of hydrogen, or 35.5 grams of chlorine or 8 grams of oxygen.
Acids : Equivalent weight of an acid = Formula weight / basicity (basicity is the number of replaceable hydrogen atoms present in the acid.)

| S.No. | Acid Formula | Basicity | Formula Wt. | Eq.Wt |
| :---: | :--- | :---: | :---: | :---: |
| 1. | HCl | 1 | 36.5 | 36.5 |
| 2. | $\mathrm{H}_{2} \mathrm{SO}_{4}$ | 2 | 98.0 | 49.0 |
| 3. | $\mathrm{H}_{2} \mathrm{C}_{2} \mathrm{O}_{4} 2 \mathrm{H}_{2} \mathrm{O}$ | 2 | 126.0 | 63.0 |
| 4. | $\mathrm{CH}_{3} \mathrm{COOH}$ | 1 | 60.0 | 60.0 |
| 5. | $\mathrm{H}_{3} \mathrm{PO}_{4}$ | 3 | 98.0 | 32.7 |

Bases : Equivalent weight of a base $=$ Formula weight $/$ Acidity (Acidity is the number of replaceable hydroxyl groups present in the base.)

| S.No. | Base Formula | Acidity | Formula Wt. | Eq.Wt |
| :---: | :--- | :---: | :---: | :---: |
| 1. | NaOH | 1 | 40 | 40 |
| 2. | $\mathrm{Ca}(\mathrm{OH})_{2}$ | 2 | 74 | 37 |
| 3. | CaO | 2 | 56 | 28 |

REDOX REAGENTS (Electron Concept) :
OXIDISING AGENT : An oxidising agent is one that gains electrons and gets reduced to a lower oxidation state.

Eq. Wt. of oxidant = Formula Wt. $/$ No. of electrons gained by one species.
Eg. 1. $\mathrm{KMnO}_{4}$ : The partial equation of $\mathrm{KMnO}_{4}$ for the reduction process may be written as follows :

$$
\mathrm{MnO}_{4}^{-}+8 \mathrm{H}^{+}+5 \mathrm{e}^{-} \longrightarrow \mathrm{Mn}^{2+}+4 \mathrm{H}_{2} \mathrm{O}
$$

The number of electrons gained is five
Eq. Wt. of $\mathrm{KMnO}_{4}=$ Formula Wt. $/ 5=158 / 5=31.6$
Eg. 2. $\mathrm{K}_{2} \mathrm{Cr}_{2} \mathrm{O}_{7}$ : The partial equation is given below

$$
\mathrm{Cr}_{2} \mathrm{O}_{7}^{2-}+14 \mathrm{H}^{+}+6 \mathrm{e}^{-} \longrightarrow 2 \mathrm{Cr}^{3+}+7 \mathrm{H}_{2} \mathrm{O}
$$

The number of electrons gained is six.
Eq. Wt. of $\mathrm{K}_{2} \mathrm{Cr}_{2} \mathrm{O}_{7}=$ Formula Wt. $/ 6=294.18 / 6=49.03$
Eq. Wt. of $\mathrm{Cr}(\mathrm{VI})=$ Formula $\mathrm{Wt} . / 3=51.9 / 3=17.3$
REDUCINGAGENT : A reducing agent is one that loses electrons and gets oxidised to a higher oxidation state.

Eq. Wt. of a reducing agent $=$ Formula Wt. No. of electrons lost by one molecule.
Eg. 1. Mohr's salt (Ferrous ammonium sulphate):

$$
\left[\mathrm{Fe}^{++}-\mathrm{e}^{-} \longrightarrow \mathrm{Fe}^{3+}\right]
$$

The no. of electrons lost is one.
Eq. Wt. of Mohr's Salt = Formula Wt. $/ 1=392.1 / 1$
Eq. Wt. of Ferrous iron $=55.85 / 1=55.85$
Eg. 2. Oxalic acid: The partial equation is as follows :

$$
\left[\mathrm{C}_{2} \mathrm{O}_{4}^{2-}-2 \mathrm{e}^{-} \longrightarrow 2 \mathrm{CO}_{2}\right]
$$

The no. of electrons lost is two.
Eq. Wt. of oxalic acid $=$ Formula Wt. of oxalic acid $/ 2=126 / 2=63$

## Precautions:

1. Students are required to go through the experimental procedure and come prepared for the experiment.
2. First clean your apparatus thoroughly with tap water and finally rinse with distilled water.
3. Rinse the pipette and burette with the solution before taking it into them.
4. No air bubble should be entered while filling the pipette or burette.
5. Never blow the pipette to expel the last drop (it is calibrated by leaving that drop in the pipette)
6. Note the reading of burette or pipette by keeping your eye exactly at the same level to avoid parallax error.
7. Take upper meniscus for colored solution and lower meniscus for colorless solution in the burette.
8. End point must be sharp (color change must be obtained by the addition of a single drop)
9. Wash your apparatus thoroughly before leaving the laboratory.
10. Girl students are advised to wear aprons while doing the experiments.

$=\quad \mathrm{gms}$

## Expt.No: <br> Date: <br> Determination of HCl using standard $\mathrm{Na}_{2} \mathrm{CO}_{3}$ solution

Aim:- To estimate the amount of HCl using standard Sodium carbonate solution
Chemicals required: 1) Standard sodium carbonate solution 2) Hydrochloric acid
Indicator: Methyl orange
Theory: Determination of an acid by using a standard alkali solution is called alkali metric method. The amount of hydrochloric acid present in the given sample can be estimated by titrating with a standard Sodium carbonate solution using methyl orange as an indicator. It is Neutralization (Acid - Base) titration. During titration the following neutralisation reaction takes place.

$$
\mathrm{Na}_{2} \mathrm{CO}_{3}+2 \mathrm{HCl} \longrightarrow 2 \mathrm{NaCl}+\mathrm{H}_{2} \mathrm{O}+\mathrm{CO}_{2}
$$

## PART -A: PREPARATION OF STANDARDED SODIUM CARBONATE SOLUTION

Procedure: - About 5.5 grams of Sodium carbonate is placed in a clean, dried weighing bottle. The weighed substance is transformed in to 100 ml volumetric flask. After transferring the substance, weight of the weighing bottle is determined

The substance in the volumetric flask is diluted by adding distilled water up to the mark. The solution is then thoroughly mixed to get homogeneous solution

## PART -B: ESTIMATION OF HYDROCHLORIC ACID

Procedure:- 10 ml of standard sodium carbonate solution is taken in a clean conical flask, 2-3 drops of methyl orange indicator are added and then the solution is titrated against the hydrochloric acid solution present in the burette till the colour changes from orange yellow to orange red. It is the end point. The titration is repeated until two successive constant values are obtained. The results are reported in a neat tabular form.

Result: - Amount of hydrochloric acid present n the given 100 ml of the hydrochloric acid solution =

TABLE-1: STANDADIZATION OF HYDROCHLORIC ACID

| :---: |
| S.No |

Normality of Std. Hydrochloric acid solution $\mathrm{N}_{2}=$ N
Volume of Hydrochloric acid consumed $=V_{3} \mathrm{ml}$
Volume of the Water sample taken $=\mathrm{V}_{4} \mathrm{ml}$

## Alkalinity of the given sample

$=\frac{\text { Normality of } \mathrm{HCl} \text { Solution }\left(\mathrm{N}_{2}\right) \times \text { Vol. of } \mathrm{HCl} \text { Solution }\left(\mathrm{V}_{3}\right) \times \text { Equiv. Wt. of } \mathrm{CaCO}_{3}(50) \times 1000}{\text { Volume of Water Sample Taken }\left(\mathrm{V}_{4}\right)}$

## Determination of Alkalinity of a sample containing $\mathrm{Na}_{2} \mathrm{CO}_{3}$ and NaOH

AIM: - To estimate the alkalinity of the given water sample containing $\mathrm{Na}_{2} \mathrm{CO}_{3}$ and NaOH
Requirements: - 1) Std Sodium Carbonate Solution 2) Hydro choric acid 3) water sample
Indicator:- Methyl orange

## Theory:-

. Alkalinity of the water sample can be estimated by titration of the water sample against a standard hydrochloric acid solution methyl orange as indicator. This is a Neutralization Titration and it involves the following chemical reactions.
(i) $\mathrm{OH}^{-}+\mathrm{H}^{+} \longrightarrow \mathrm{H}_{2} \mathrm{O}$
(ii) $\mathrm{CO}_{3}{ }^{2-}+\mathrm{H}^{+} \longrightarrow \mathrm{HCO}_{3}{ }^{-}$
(iii) $\mathrm{HCO}_{3}^{-}+\mathrm{H}^{+} \longrightarrow \mathrm{H}_{2} \mathrm{O}+\mathrm{CO}_{2}$

The titration of the water sample against a standard acid solution using methyl orange indicator marks the completion of all the above three reactions.

The acid solution is to be standardized with standard sodium carbonate solution using methyl orange indicator.

## PART - A: Standardisation of hydrochloric acid solution:

10 ml of the standard sodium carbonate solution is pipetted out in to a clean conical flask 23 ,drops of methyl orange indicator is added and then the solution is titrated against hydro choric acid present in the burette until the colour changes from orange yellow to orange red. It indicates the end point. The titration is repeated until two successive constant values are obtained

## PART - B: ESTIMATION OF THE ALKALINITY OF THE GIVEN WATER SAMPLE

10 ml of the water sample is pipette out in to a clan conical flask. 2-3, drops of methyl orange indicator is added and then the solution is titrated against hydro choric acid present in the burette until the colour changes from orange yellow to orange red. It indicates the end point. The titration is repeated until two successive constant values are obtained

Result:- Alkalinity of the given water sample =

## Preparation of the standard Oxalic acid solution

|  |  | Initial <br> $(\mathrm{ml})$. | Final <br> $(\mathrm{ml})$. | Slonn |
| 1 |  |  |  |  |
| 2 |  |  |  |  |
| 3 |  |  |  |  |
| 4 |  |  |  |  |

| Std Oxalic acid solution | Potassium permanganate solution |
| :---: | :---: |
| $\mathrm{N}_{1}:$ Normality of Std oxalic acid <br> Solution $=\ldots \ldots \ldots \mathrm{N}$ | $\mathrm{V}_{2}:$ Volume of potassium permanganate <br> solution $=\quad \ldots \ldots$. ml. |
| $\mathrm{V}_{1}:$ Volume of Std oxalic acid <br> solution $=\quad \ldots \ldots . \mathrm{ml}$. | $\mathrm{N}_{2}:$ Normality of potassium <br> permanganate <br> Solution $=\ldots \ldots \ldots \mathrm{N}$ |

Normality of potassium permanganate Solution $N_{2}=\frac{N_{1} x V_{1}}{V_{2}}$
$=$

Amount of the $\mathrm{Mn}(\mathrm{II})$ present in given 100 ml . of the $\mathrm{KMnO}_{4}$ Solution
Normality of $\mathrm{KMnO}_{4}$ Solution $\left(\mathrm{N}_{2}\right)$ x Equivalent Weight of Mn (27.5) x 100
1000

$$
=
$$

$=\quad$....gms

## Determination of Mn (II) using standard Oxalic acid solution

AIM: - To determine the normality and estimate the amount Mn (II) present in the given
100 ml of the solution by using Oxalic acid solution.
Chemicals required:1)) Oxalic acid solution
2) Potassium permanganate solution
3) 6N Sulphuric acid
Indicator: Potassium permanganate (self indicator)

THEORY: - The amount of Mn (II) present in the given sample can be estimated by titration with a Standard Oxalic acid solution. It is a redox type of titration. as it involves both reducing agent and oxidising agent. Here Mn (II) solution acts as an oxidizing agent and oxalic acid act as reducing agent.
$2 \mathrm{KMnO}_{4}+3 \mathrm{H}_{2} \mathrm{SO}_{4} \longrightarrow \mathrm{~K}_{2} \mathrm{SO}_{4}+2 \mathrm{MnSO}_{4}+3 \mathrm{H}_{2} \mathrm{O}+5[\mathrm{O}] \quad$ (Reduction)
$5 \mathrm{H}_{2} \mathrm{C}_{2} \mathrm{O}_{4}+5[\mathrm{O}] \longrightarrow \mathrm{CO}_{2}+5 \mathrm{H}_{2} \mathrm{O} \longrightarrow$ (Oxidation)
$2 \mathrm{KMnO}_{4}+5 \mathrm{H}_{2} \mathrm{C}_{2} \mathrm{O}_{4}+3 \mathrm{H}_{2} \mathrm{SO}_{4} \longrightarrow \mathrm{~K}_{2} \mathrm{SO}_{4}+2 \mathrm{MnSO}_{4}+10 \mathrm{CO}_{2}+8 \mathrm{H}_{2} \mathrm{o}$ (Redox)
Role of sulphuric acid is to provide acidity. Here, no indicator is used because potassium permanganate solution itself acts as a self-indicator.

## PART -A: Preparation of the standard Oxalic acid solution

Procedure: - About 6.5 grams of oxalic acid is placed in a clean, dried weighing bottle. The weighed substance is transformed in to 100 ml volumetric flask. After transferring the substance, weight of the weighing bottle is determined

The substance in the volumetric flask is diluted by adding distilled water up to the mark. The solution is then thoroughly mixed to get homogeneous solution

## PART B: DETERMINATION OF POTASSIUM PERMANGANATE

10 ml of the Standard oxalic acid solution is pipetted out in to a clean conical flask, 5 ml of 6 N sulphuric acid is added to this solution and then the solution is heated to $60-70^{\circ} \mathrm{C}$. Now the hot solution is titrated against potassium permanganate present in the burette drop by drop till to get permanent pale pink colour. It is the end point. The titration is repeated until two successive constant values are obtained.

Result:- Amount of the Mn (II) present in the given 100 ml of the $\mathrm{KMnO}_{4}$ solution $=$

## Preparation of the standard Potassium dichromate solution

$\mathrm{W}_{1}=$ Weight of the weighing bottle + substance $=$
$\mathrm{W}_{2}=$ Weight of the weighing bottle after transferring the substance $=$
Weight of the substance transferred $\left(\mathrm{W}_{1}-\mathrm{W}_{2}\right)=$

$=\quad$ gms

## ESTIMATION OF FERROUS IRON - DICHROMETRY

Aim:- To determine the normality and estimate the amount ferrous iron present in the given 100 ml ferrous iron sample by using Standard $\mathrm{K}_{2} \mathrm{Cr}_{2} \mathrm{O}_{7}$ solution.

Chemicals required:- 1). Std potassium dichromate solution 2). Mohr's salt solution
3). Sulphuric acid 4). Phosphoric acid

Indicator: - Di-phenyl Amine
THEORY:-The amount of ferrous iron present in the given sample can be estimated by titrating against a standard $\mathrm{K}_{2} \mathrm{Cr}_{2} \mathrm{O}_{7}$ solution. It is a redox type of titration. In this titration chromium (V1) Solution act as an Oxidizing agent and Mohr's salt solution act as reducing agent.

## Reactions in Molecular Form

$\mathrm{K}_{2} \mathrm{Cr}_{2} \mathrm{O}_{7}+4 \mathrm{H}_{2} \mathrm{SO}_{4} \longrightarrow \mathrm{~K}_{2} \mathrm{SO}_{4}+\mathrm{Cr}_{2}\left(\mathrm{SO}_{4}\right)_{3}+4 \mathrm{H}_{2} \mathrm{O}+3[\mathrm{O}] \quad \ldots$ (Reduction)
$3\left[2 \mathrm{FeSO}_{4}+\mathrm{H}_{2} \mathrm{SO}_{4}+[\mathrm{O}] \longrightarrow \mathrm{Fe}_{2}\left(\mathrm{SO}_{4}\right)_{3}+\mathrm{H}_{2} \mathrm{O}\right] \quad \ldots$ (Oxidation)
$\mathrm{K}_{2} \mathrm{Cr}_{2} \mathrm{O}_{7}+6 \mathrm{FeSO}_{4}+7 \mathrm{H}_{2} \mathrm{SO}_{4} \longrightarrow 3 \mathrm{Fe}_{2}\left(\mathrm{SO}_{4}\right)_{3}+\mathrm{K}_{2} \mathrm{SO}_{4}+\mathrm{Cr}_{2}\left(\mathrm{SO}_{4}\right)_{3}+7 \mathrm{H}_{2} \mathrm{O}$ (Redox)
Role of sulphuric acid, in this titration is to provide acidity. Indicator used is the diphenyl amine. The titration of iron with diphenyl amine indicator must be performed in the presence of phosphoric acid because phosphoric acid increases the efficiency of the indicator

## PART -A: Preparation of the standard Potassium dichromate solution

About 0.49 grams of potassium dichromate acid is placed in a clean, dried weighing bottle. The weighed substance is transformed in to 100 ml volumetric flask. After transferring the substance, weight of the weighing bottle is determined

The substance in the volumetric flask is diluted by adding distilled water up to the mark. The solution is then thoroughly mixed to get homogeneous solution

## PART B: - ESTIMATION OF FERROUS IRON

The given unknown Mohr's Salt Solution present in the volumetric flask is diluted up to the mark by adding distilled water and then the solution is thoroughly mixed in order to get homogeneous solution. 10 ml of the standard Mohr's salt solution is pipetted out in to a clean conical flask. 10 ml of dilute sulphuric acid, 5 ml of phosphoric acid and 2-3 drops of diphenyl amine indicator are added to the Mohr's salt solution present in the conical flask. This colourless solution is titrated against the potassium dichromate solution, taken in the burette until to get green colour, bluish green colour and finally bluish violet colour at the end point.

RESULT :-Amount of ferrous iron present in the given 100 ml of the solution

$$
=\quad \mathrm{gms}
$$

# Determination of copper (II) using standard Hypo solution 

AIM:- To determine the normality and estimate the amount of copper present in the given 100 ml of the copper solution by using hypo solution

Chemicals required:- 1).Std Copper sulphate solution 2) Sodium thiosulphate solution 4) Potassium iodide 4) Unknown copper solution

Indicator: - Starch
Theory:-The amount of copper present in the given unknown copper solution can be estimated by titrating with standard sodium thiosulphate solution using starch as an indicator.
$2 \mathrm{CuSO}_{4}+4 \mathrm{KI} \longrightarrow 2 \mathrm{CuI} \downarrow+2 \mathrm{~K}_{2} \mathrm{SO}_{4}+\mathrm{I}_{2} \quad \ldots \ldots$ (Oxidation)
$2 \mathrm{Na}_{2} \mathrm{~S}_{2} \mathrm{O}_{3}+\mathrm{I}_{2} \longrightarrow 2 \mathrm{NaI}+\mathrm{Na}_{2} \mathrm{~S}_{4} \mathrm{O}_{6} \quad \ldots \ldots$. (Reduction)
$2 \mathrm{CuSO}_{4}+4 \mathrm{KI}+2 \mathrm{Na}_{2} \mathrm{~S}_{2} \mathrm{O}_{3} \longrightarrow 2 \mathrm{CuI} \downarrow+2 \mathrm{~K}_{2} \mathrm{SO}_{4}+2 \mathrm{NaI}+\mathrm{Na}_{2} \mathrm{~S}_{4} \mathrm{O}_{6}$ (Sparingly Soluble) (Sodium tetrathionate)

The above equations show that each copper ion $\left(\mathrm{Cu}^{++}\right)$gains an electron from the iodide ion $\left(\mathrm{I}^{-}\right)$and is reduced to mono valent cuprous ion $\left(\mathrm{Cu}^{+}\right)$, which is then precipitated in the form of the sparingly soluble cuprous iodide (Cu I) with liberation of copper equivalent amount of iodine. The liberated free iodine is then titrated against the standard sodium thiosulphate solution, using starch as an indicator. The sodium thiosulphate solution must be standardized by titrating it against standard copper sulphate solution using starch as indicator.

## PART A:-STANDADISATION OF SODIUM THIOSULPHATE SOLUTION

10 ml of the Standard Copper sulphate solution is pipetted out in to a clean conical flask. 10 ml . of $10 \%$ potassium iodide solution is added to this solution. The flask is covered with a watch glass for about 2-3 minutes in order to prevent the escape of the liberated iodine. Then, the watch-glass is removed out and then the solution is titrated against sodium thiosulphate solution present in the burette until the colour changes to pale yellow. At this stage add two ml of starch indicator. As it results the colour changes to blue. Continue the titration with sodium thiosulphate present in burette until the blue colour disappears. It indicates the end point. The titration is repeated until two successive constant values are obtained

## PARTB:- ESTIMATION OF COPPER

The given unknown Copper solution present in the volumetric flask is diluted up to the mark by adding distilled water and then the solution is thoroughly mixed in order to get homogeneous solution. 10 ml of this solution is pipette out in to a clean conical flask, 10 ml . of $10 \%$ potassium iodide solution is added to the copper solution. The flask is covered with a watch glass for about 2-3, minutes in order to complete the liberation of iodine. Then, the watch-glass is removed out and then the solution titrated against sodium thiosulphate present in the burette until the colour changes from reddish brown to pale yellow. At this stage add two ml of starch indicator. As it results the colour changes to blue. Now the solution is titrated against sodium thiosulphate present in burette until the blue colour disappears. It indicates the end point. The titration is repeated until two successive constant values are obtained

Result:- Amount of the copper present in the given 100 ml of the sample $=$

## DETERMINATION OF TEMPORARY AND PERMANENT HARDNESS

AIM:-To determine the temporary and permanent hardness of the given water sample by using the E.D.T.A. solution.

Chemicals required: - 1) Std Zinc solution 2) E.D.T.A. solution 3) $\left(\mathrm{NH}_{4} \mathrm{Cl}+\mathrm{NH}_{4} \mathrm{OH}\right)$ Buffer solution 4) Water sample.

Indicator: - Eriochrome Black-T
THEORY: - Total hardness is the sum of temporary hardness and permanent hardness. Temporary hardness is due to bicarbonates of calcium and magnesium. The permanent hardness is due to chlorides and sulphates of calcium and magnesium. The total hardness of the given water sample can be estimated by titration with standard E.D.T.A. solution using Eriochrome Black-T as an indicator It is a complexometric titration as it involves the formation of a soluble complexes.

In this determination, the water sample is made as alkaline by the addition of $\left(\mathrm{NH}_{4} \mathrm{OH}+\mathrm{NH}_{4} \mathrm{Cl}\right)$ buffer solution in order to maintain the pH in the range 10 , because the complex formation takes place at this pH only. When indicator is added to the buffered water sample, then it forms less stable metal indicator complexes, which are wine red in colour.

When the wine-red coloured solution is titrated with a standard E.D.T.A. solution, then the less stable Metal-indicator $[M-R]$ complexes are decomposed to more stable Metal-EDTA complexes, with the liberation of the indicator ions $\left(\mathrm{R}^{--}\right)$in the solution. At the equivalence point, the wine-red colour of the solution changes to blue owing to accumulation of the indicator ions.
$\mathrm{M}-\mathrm{R}+$ E.D.T.A $\longrightarrow \quad \longrightarrow$ [M--EDTA] + Indicator
Wine-red Blue

The E.D.T.A. solution can be standardized using standard zinc solution and Eriochrome Black-T indicator.

## PART A:-STANDARDISATION OF E. D. T. A. SOLUTION

10 ml of standard zinc solution is pipetted out in to a clean conical flask. 2 ml of the buffer solution and 3-4 drops of the of the E.B.T. indicator are added. The solution is now titrated against the E.D.T.A. solution until the colour of the solution is changed from wine red to blue at the end point. The titration is repeated until two successive constant values are obtained

## PART B:-ESTIMATION OF TOTAL HARDNESS

10 ml of the water sample is pipette out into a clean conical flask. 2 ml of the buffer solution and 3-4 drops of the of the E.B.T. indicator are added. The solution is now titrated against the std E.D.T.A. solution until the colour of the solution is changed from wine red to blue at the end point. The titration is repeated until two successive constant values are obtained.

$=$
= ----------- P.P.M

## PART C:-ESTIMATION OF PERMANENT HARDNESS

The given water sample is boiled for 30 minutes and then filterd. 10 ml of the filtrate water sample is pipetted out into a clean conical flask. 2 ml of the buffer solution and 3-4 drops of the of the E.B.T. indicator are added. The solution is now titrated against the std E.D.T.A. solution until the colour of the solution is changed from wine red to blue at the end point. The titration is repeated until two successive constant values are obtained

## PART D:-ESTIMATION OF TEMPORARY HARDNESS

Temporary harness can be calculated by subtracting the permanent harness from total hardness.

Temporary hardness of the given water sample =Total hardness ---- permanent hardness
$=\quad \mathrm{ppm}$.

Result:- Total hardness of the given water sample $=$ Temporary hardness of the given water sample $=$ Permanent hardness of the given water sample $=$

c = Concentration (M).
I = pathlength (cm).
```

Result:- The concentration of $\mathrm{Fe}^{3+}$ in the given sample $=$

## DETERMINATION OF IRON BY A COLORIMETRIC METHOD

AIM: - To determine the amount of Iron present in the given 100 ml of the Iron solution by a calorimetric method using thiocyanate as reagent.

Apparatus:- Spectrophotometer, Burette, Pipette, Cuvette
Chemicals required: - 1) Stock iron solution ,2). $20 \%$ Pottasium thiocyanate solution, 3) $4 \mathrm{M} \mathrm{HNO}_{3}$

Theory: When a monochromatic light of intensity $\mathrm{I}_{0}$ is incident on a transparent medium, a part $I_{a}$ is absorbed, a part of $I_{r}$ is reflected and the remaining part $I_{t}$ is transmitted.

$$
\mathrm{I}_{0}=\mathrm{I}_{\mathrm{a}}+\mathrm{I}_{\mathrm{r}}+\mathrm{I}_{\mathrm{t}}
$$

For a glass - air interface $\mathrm{I}_{\mathrm{r}}$ is negligible. Therefore

$$
\mathrm{I}_{0}=\mathrm{I}_{\mathrm{a}}+\mathrm{It}
$$

$\mathrm{I}_{\mathrm{t}} / \mathrm{I}_{0}=\mathrm{T}$ called Transmittance. $\log 1 / \mathrm{T}=\log \mathrm{I}_{0} / \mathrm{I}_{\mathrm{t}}$ is called the absorbance or optical density.
The relationship between absorbance A, Concentration C (expressed in mol/lit) and path length $t$ (expressed in cm ) is given by Beer- Lambert's law

$$
\mathbf{A}=\log \mathrm{I}_{0} / \mathrm{I}_{\mathrm{t}}=\mathrm{Ect}
$$

Where e is the molar extinction coefficient, E is a constant for a given substance at a given wave length. If the path length is (cell thickness) kept constant, then A c.
Hence a plot of absorbance against concentration gives a straight line as shown in figure (Calibration curve).The colour is measured using a Spectrophotometer at a wave length where the absorbance is maximum.
Ferric iron forms a red coloured complex with thiocyanate ion, $\left[\mathrm{Fe}(\mathrm{SCN})_{\mathrm{x}}\right]$ in acid medium. Beer- Lambert's law obeyed in dilute solution. The colour of the complex is not stable and hence should be measured within 5 minutes after producing colour. The optical densities are measured by a photocolorimeter and the concentration of ferric iron is obtained from a standard curve.

$$
\mathrm{Fe}^{3+}+6 \mathrm{SCN}^{-} \longrightarrow\left[\mathrm{Fe}(\mathrm{SCN})_{6}\right]^{3-}
$$

## Procedure:-

## Preparation of the standard calibration curve.

Dissolve the given ferrous ammonium sulphate in 100 ml of water and 5 ml of $1: 5 \mathrm{H}_{2} \mathrm{SO}_{4}$ dilute the solution through $\mathrm{KMnO}_{4}$ present in the burette until light pink colour appears. Dilute the solution to 1 litre such that 1 ml of solution contains 0.1 mg of $\mathrm{Fe}^{3+}$. From the above solution take separately $1,2,3,4,5 \mathrm{ml}$ in to five 100 ml standard volumetric flasks. Add 1 ml of 4 M nitric acid and 5 ml of $40 \%$ potassium thiocyanate solution to all the samples to get blood red colour and made up to the mark by adding distilled water. Now measure the optical densities of all five samples using Photo colorimeter. Plot a graph by taking amount of ferrous iron on X - axis and optical densities on Y - axis. The curve obtained is called calibration curve. Concentration of the sample is determined from the graph.

Table:-Determination of the $\mathrm{PH}^{\mathrm{H}}$ of the given solution of $50 \mathrm{ml} 0.1 \mathrm{~N} \mathrm{CH}_{3} \mathrm{COOH}$ with 0.1 N NaOH

## Determination of the concentration of acetic acid using Sodium hydroxide $\mathrm{PH}^{\mathrm{H}}$ metry method

Aim: - To determine the strength of the acetic acid solution by titrating against NaOH solution by using pH meter.
Requirements: - Beakers ( 500 ml ), Burette, Glass electrode, Reference electrode, StirrerChemicals:- 0.1 N NaOH solution ; 0.1 N acetic acid, Buffer Tablets $\mathrm{pH} 4 \& 7$. Distilled water

Theory: - The concentration of solutions expressed in terms of normality. However to express very small concentrations of $\mathrm{H}^{+}$ions, pH scale is used. pH can be measured directly with the help of pH meter. The acidic, alkaline or neutral nature of solution depends on the pH value PH is defined as negative logerthem of hydrogen ion concentration.

$$
\mathrm{PH}=----\log \mathrm{H}^{+}
$$

Example: Titration of 50.0 mL of $0.100 \mathrm{~N} \mathrm{CH}_{3} \mathrm{COOH}$ with 0.100 N NaOH .
Net reaction: $\mathrm{CH}_{3} \mathrm{COOH} \quad \mathrm{NaOH} \quad \mathrm{CH}_{3} \mathbf{C O O N a} \quad \mathrm{H}_{2} \mathrm{O}$
Equivalence point $\mathrm{pH}>7$ •
Smaller change in pH near equivalence point $\cdot$
Before equivalence point the pH is nearly constant (buffer) •
After equivalence point the pH depends on excess of standard base

## Procedure: -

1. Glass electrode and reference electrode are washed with water and then dipped in distilled water
2. Turn ' ON 'the pH meter \& Calibrate the pH meter by using standard buffer solutions of $\mathrm{pH} 4 \& 7$.
3. 10 ml of the acid solution is pipetted out in to a clean beaker.
4. Turn 'ON 'the pH meter and note down the pH of the solution.
5. Add ml of the NaOH solution and note down the pH of the solution
6. Continue the process by adding NaOH solution and note down the pH of the solution
7. Then concentration of the solution is calculated.

In diprotic amino acids such as glycine, The pI is an average of the pKa 's of the carboxyl (2.34) and ammonium (9.60) groups. Thus, the pI for alanine is calculated to be: $(2.34+9.60) / 2=5.97$

## Determination of Isoelectric point of Amino acid by PH metric method

To determine isoelectric point (pI) of Amino acid by Ph metric method
Titration stand,Burette, Ph meter,
Amino acids consist of: a basic amino group ( -NH 2 ) \& an acidic carboxyl group ( -COOH ) a hydrogen atom $(-H)$, a distinctive side chain $(-\mathrm{R})$.

Amino acids are Amphoteric which means it can react as an acid (donate a proton) as well as a base (accept a proton) •

Amphoteric properties of amino acids are due to the presence of their ionizable a-amino and a-carboxylic group can act sometimes as acids and sometimes as bases depending on the pH of their media. -

PH at which aminoacid has no net charge is called isoelectric point. Amino acid at this point has Zwitter ionic form

Each amino acid have a different isoelectric point (pI) •
pI : It is the pH value at which the positive charge equals the negative charge (i.e. the net charge of this molecule equals zero) (zwitter ion)

Amino acids have more than one pka, because it is polyprotic (contain more than one ionizable groups).

1. At a very low pH (acidic) both groups are fully protonated where the solution predominantly contains:
2. When the pH is raised, the -COOH group start to be deprotonated and the proportion will be
3. $\mathrm{pH}=\mathrm{pKa1}$, where it will act as a buffer and the solution will contain an equal amount of 4- Further increase in pH , the solution will predominantly contains zwitter ion and the pH at this point is equal to pI .

5- As the pH increases, the second group -NH3 + will be deprotonated
6- After that, $\mathrm{pH}=\mathrm{pKa} 2$ where it will as a buffer and the solution will contain an equal amount of
7- the NH3 + group will dissociate and at the same time the glycine full dissociate in end point Procedure

Pipette 10 ml of glycine solution ( 0.1 M ) into a 50 ml breaker. •
Add 0.5 ml of $(0.1 \mathrm{M}) \mathrm{HCl}$ from the burette and determine the pH of the solution after each addition. - Continue adding acid in until pH falls to about 1.3 . •

Wash the electrode in distilled water titrate a further 10 ml of glycine solution with 0.1 M
NaOH until pH reaches 12.5. •
Plot a titration curve for gluycine ( pH verses titrant in ml ). •
Record the titration table and Plot a Curve of pH versus ml of NaOH and HCl added. •
Determine the pka and pI values from your curves and compare them with the standard values. •

For glycine: $\mathrm{pK} 1=2.34, \mathrm{pK} 2=9.69, \mathrm{pI}=6.01$ •
Titration curve of amino acid (glycine)

Table:- Titration between HCl and 0.1 N NaOH solution.

## CONDUCTOMETRIC TITRATION STRONG ACID VERSES STRONG BASE

> Aim: - To determine the strength of the Hydrochloric acid solution by titrating against NaOH solution conductometrically.

Requirements:- Conductivity meter, Conductivity cell, Beakers (500ml), Burette, pipette, stirrer
Chemicals:- 0.1 NaOH solution ; HCl sample, distilled water,
Theory:-The electrical conductance of the solution depends upon the number of the ions and their mobilities. When sodium hydroxide solution is added to the Hydro chloric acid solution, their conductivities are deceased .It is due to replacement of highly mobile H ions by less mobile Na ions. Conductivity keeps on decreasing until to reach the end point. At the equivalent point solution contains Na and Cl ions. Further addition of NaOH increases the conductivity, which is due to high momilities of the OH ions.

$$
\mathrm{HCl}+\mathrm{NaOH} \longrightarrow \mathrm{NaCl}+\mathrm{H}_{2} \mathrm{O}
$$

## Procedure:-

1. Take 10 ml of the given HCl solution in a 100 ml beaker.

Add 40 ml of distilled water and stir it.
2. Wash the conductivity cell with distilled water and then rinse it with the given HCl solution. Dip the cell in to the solution taken in a beaker.
3. Initial conductance of the solution is measured.
4. Take 0.1 N NaOH solution in a burette and fixed to stand.
5. Add 0.5 ml of NaOH into the beaker containg HCl ,stir well and measure their conductivity.
6. Continue the procedure by adding 0.5 ml of NaOH and note down the corresponding conductivity in the Table.
7. Initially, the conductivity decreases, reaches the minimum value and then increases. At least 5 or 6 readings must be taken after the minimum value.
9. Plot the graph between conductances on Y - axis Vs volume of NaOH added on X - axis
10. The point of interaction will give the amount of alkali required for neutralization of the acid.

Modal graph

Table:- Potentiometric Titration between Strong Acid Vs weak base

\end{array}
$$

$\mathrm{N}_{\mathrm{HCl}}=\begin{gathered}\mathrm{N}_{\mathrm{NaOH}} \mathrm{X} \mathrm{V}_{\mathrm{NaOH}} \\ \mathrm{V}_{\mathrm{HCl}}\end{gathered}$

$$
=0.1 \times----/ 10
$$

Result:- Normality of the given Hydrochloric acid solution =

## POTENTIOMETRIC TITRATION BETWEEN STRONG ACID AND STRONG BASE

Aim: - To determine the strength of the Hydrochloric acid solution by titrating against NaOH solution potentiometrically.

Requirements:- potentiometer, calomel and platinum electrodes, , Beakers (500ml), Burette, pipette, stirrer

Chemicals:- 0.1 NaOH solution ; HCl sample solution , distilled water
Theory;- Potentiometric titration is a volumetric method in which the potential between two electrodes are measured as a function of added reagent volume. In this titration, indicator electrode (the electrode which responds to change in concentration of ions in solution) is combined with reference electrode to form a complete cell. During the titration EMF of the cell is measured.

$$
\text { EMF of the cell }=\mathrm{E}_{\text {indicator }}-\mathrm{E}_{\text {reference }}+\mathrm{E}_{\text {solution }}
$$

As the concentration of the ions $\left(\mathrm{H}^{+}\right.$or $\left.\mathrm{OH}^{-}\right)$around the electrode changes, E cell also changes correspondingly in acid base titrations.
The EMF of the cell changes gradually till the end point and rapidly at very close to the end point and then gradually changes after the end point.

$$
\mathrm{HCl}+\mathrm{NaOH} \longrightarrow \mathrm{NaCl}+\mathrm{H}_{2} \mathrm{O}
$$

## Procedure:-

1. The 10 ml of the HCl solution is pipette out in to a clean 100 ml beaker provided with a stirrer.
2. The platinum and calomel electrodes immersed in the solution are connected to negative and positive terminals of the potentiometer.
3. Initial EMF of the solution is noted.
4. 0.1 NNaOH solution is taken in burette and added 0.5 ml additions to the beaker and the corresponding potential is noted after stirring.
5. Continue the titration by adding 0.5 ml of alkali solution. Take three to four readings after the equivalent point. Record the volume of alkali added and EMF of the solution.
6. The same experiment is repeated with addition of 0.1 ml of NaOH solution.
7. A graph is plotted between the emf or $\mathrm{E} / \mathrm{V}$ on Y - axis and the volume of the solution on X - axis.

The maximum of the curve obtained from the graph represents the end point

## Model graph

Table:- Titration of the egg solution with NaOH solution

Volume of eggshells solution taken $=25 \mathrm{ml}$ Volume of NaOH used $=$

## Determination of Calcium carbonate in eggshells - Back Titration

The major component of eggshells is calcium carbonate $\left(\mathrm{CaCO}_{3}\right)$. This analysis is done by reacting the calcium with acids. Calcium carbonate is insoluble in pure water but will dissolve in acid.

$$
\mathrm{CaCO}_{3}(\mathrm{~s})+2 \mathrm{HCl}(\mathrm{aq}) \rightarrow \mathrm{CaCl}_{2}(\mathrm{aq})+\mathrm{H}_{2} \mathrm{O}(\mathrm{l})+\mathrm{CO}_{2}(\mathrm{~g})
$$

## Back Titration Technique

This reaction cannot be used directly to titrate the $\mathrm{CaCO}_{3}$ because it is very slow when the reaction is close to completion (endpoint). Instead, the determination is achieved by adding an excess of acid to dissolve all of the $\mathrm{CaCO}_{3}$ and then titrating the remaining excess HCl with NaOH solution to determine the amount of acid that did not react with the calcium carbonate. The difference between amounts of the acid $(\mathrm{HCl})$ initially added and the amount left over after the reaction is equal to the amount that is used by the $\mathrm{CaCO}_{3}$. From this, the amount of $\mathrm{CaCO}_{3}$ in the sample can be calculated. The reaction used to determine the leftover acid is

$$
\mathrm{HCl}(\mathrm{aq})+\mathrm{NaOH}(\mathrm{aq}) \rightarrow \mathrm{NaCl}(\mathrm{aq})+\mathrm{H}_{2} \mathrm{O}(\mathrm{l})
$$

## Method

1. Wash the egg shell with deionized water and peel off all of the membranes from the inside of the shell. If you leave the membranes, the proteins in the membrane will react with the sodium hydroxide and give poor results.
2. Dry the shell for about 10 minutes in the oven and grind the shell to a fine powder.
3. Weigh 1 g of the dried shell and place into flask.
4. Pipet 25 mL of 1 M HCl to the flask containing eggshell.
5. Heat the solution on a hotplate until it just begins to boil and then allow it to cool.
6. Add a few drops of bromophenol blue indicator to the flask. (Bromophenol blue indicator is yellow in acidic solution and blue in basic solution).
7. Titrate the solution with a standardised solution of sodium hydroxide.

The end point is recorded.

Table:-Determination of Vitamin - C

| S.No | Volume of Ascorbic acid | Burette readings |  | Volume of Iodine solution |
| :---: | :---: | :---: | :---: | :---: |
|  |  | Initial | Final |  |
| 1 | 20 ml |  |  |  |
| 2 | 20 ml |  |  |  |
| 3 | 20 ml |  |  |  |

| 20 ml of standard vitamin -c required | $=\quad \mathrm{ml}$ of iodine solution |
| :--- | :--- |
| 100 ml of standard vitamin c contains | $=0.250 \mathrm{gms}$ of vitamnin c |
| 20 ml of standard vitamin c contains | $=?$ |

$$
\begin{aligned}
\text { Amount of vitamin c in } 20 \mathrm{ml} \text { of standard vitamin c solution } & =\begin{array}{c}
0.25 \times----------- \\
--100
\end{array} \\
& =0.05 \mathrm{gms}
\end{aligned}
$$

For 0.05 grams of vitamin $-C$ required $\quad \mathrm{x} \mathrm{ml}$ of iodine solution.
For titration 20 ml of sample solution requires y ml of iodine solution.
Amount of vitamin -C in sample solution $=\frac{0.05 x \text { y }}{-------\quad} \quad=\mathrm{Z} \mathrm{gms} / 100 \mathrm{ml}$
Amount of vitamin c in present in 1000 ml of the sample solution $=10 \times \mathrm{Z}$

$$
=10 \times \ldots . . . . . \quad / \mathrm{gms} / 1
$$

## DETERMINATION OF VITAMIN - C

Aim :-Estimation of Vitamin -C (Ascorbic acid)

Chemical required: - Vitamin-c tablet, 0.05 M Iodine solution, KI and Iodine, 3 M sulphuric acid

## Indicator :- Starch

Theory:-Vitamin-c is also called as ascorbic acid, an important Antioxidant. It can easily Oxidised to de hydro ascorbic acid. When iodine is added during the titration, the acid is oxidised to de hydro ascorbic acid, while the iodine is reduced to Iodide ions.

Ascorbic Acid $+\mathrm{I}_{2} \longrightarrow 2 \mathrm{I}^{-}+$De hydro ascorbic acid

Iodine is reduced to Iodide as long as Ascorbic acid is present, when all the Ascorbic acid is Oxidised, then the excess iodine is turn to react with starch and forms Blue - black starch Iodide complex. This is the end point of titration.

## Sample preparations:-

Vitamin C- :-Dissolve 0.250 gms of Vitamin -c in 100 ml of distilled water.

## Iodine Solution:-

Dissolve 2 grams of KI and 1.03 g of Iodine in 200 ml distilled water. Ad 30 ml of 3 M sulphuric and made the solution up to 1 litre by adding distilled water.

## Standardization of Iodine solution with vitamin C standard solution

Pipette out 20 ml of Vitamin C solution into a 250 ml conical flask .add 10 drops of $1 \%$ starch solution. Rinse the burette with iodine solution and fill the burette with iodine solution. Then titrate the vitamin C standard solution with iodine solution till blue back colour is obtained. Let the titre valve be x ml .

## Estimation of ascorbic acid

Pipette out 20 ml of the sample in to 250 ml conical flask and add 150 ml of distilled water and 1 ml of the starch indicator. Then titrate the sample solution against 0.005 molar Iodine solution present in the burette till persistent Blue - Black colour at the point is due to the formation of starch - iodide complex. Repeat the titration until to get two same values. Let the titre valve be y ml .

Then we can calculate how much amount of vitamin-c is present in the given sample.

## PHENOL FORMALDEHYDE

Aim: To prepare phenol formaldehyde resin

## Requirements:

(i) Apparatus: 500 ml . Beaker(glass), Glass-Rod and Measuring jar.
(ii) Chemicals: Acetic acid(glacial), Formaldehyde, Phenol and Conc. HCl

Theory: Phenolic Resins are the condensation products of phenol or phenolic derivatives and aldehydes. These resins are also called phenol-plasts. Bakelite was the earliest thermosetting resin named after its discoverer, Dr. L.H. Bakeland who patented it in 1909. It was prepared by condensation of phenol and formaldehyde. Today, there are several types of phenol formaldehyde resins which are extensively used in a variety of applications such as watersoluble adhesives, laminationg adhesives, varnish and lacquer resins and thermosetting moulding powders. The nature of the product formed depends upon:
(i) The proportion of the reactants, Phenol and Formaldehyde, and
(ii) The nature of the catalyst used, i.e. acidic or basic.

If the mole ratio of phenol to formaldehyde $(P / F)$ is greater than one (if Phenol is in excess), the reaction proceeds in an almost linear fashion. On the other hand, if the mole ratio $P / F$ is lesser than one (if formaldehyde is in excess) and if alkaline catalyst is present, three dimensional structure would be formed.
(a) Methylolation: The first step in the reaction between phenol and formaldehyde is the formation of addition compounds known as methylol derivatives; the methylol groups get attached at ortho and para-positions. These methylol derivatives may be considered as the monomers for subsequent polymerisation. These are formed under neutral or alkaline conditions.
(b) Novolac formation: In the presence of an acid catalyst and with the mole ratio of phenol to formaldehyde greater than 1, the methylol derivatives condense with phenol to first form dihydroxy - diphenyl methane(methylene bridge formation). On further condensation, fusible and soluble linear low polymers called "Novolacs" are formed, which have the structure where ortho and para links occur at random.
(c) Resole formation: In the presence of alkaline catalyst and with more formaldehyde (i.e. P/F less than 1), the methylol phenols can condense either through methylene linkages or through other linkages. In the latter case, subsequent loss of formaldehyde may occur with methylene bridge formation. The formation of products of this type which are soluble and fusible but containing alcohol groups are called resoles. If the reactions leading to their formation are carried further, large numbers of phenolic nuclei can condense to give network structure.

Trimethylol Phenol

Production of phenolic resins: The formation of resoles and novolacs, respectively, leads to the production of phenolic resins by one-stage and two-stage processes.
One-stage Resin: For producing a one-stage phenolic resin, all the reactants for the final polymer (i.e. phenol, formaldehyde and catalyst ) are charged into resin kettle and allowed to react together. The ratio of phenol to formaldehyde is about 1:1.25 and an alkaline catalyst is used.
Two-stage Resins: These resins are prepared with an acid catalyst, and only part of the necessary formaldehyde is added to the kettle, producing a mole ratio of phenol to formaldehyde of about 1:0.8. The rest is added later in the form of hexamethylenetetramine, which decomposes in the final curing step, with heat and moisture present, to yield formaldehyde and ammonia which acts as a catalyst for curing.

Resin formation: The procedures for one-and two-stage resins are similar and the same equipment is used for both. The reaction is exothermic and cooling is necessary. The formation of a resole or a novolac is evidenced by an increase in viscosity. Water is then driven off under vacuum and a thermoplastic A-stage resin, soluble in organic solvents, remains. This is taken out of the kettle and ground to fine powder. At this stage, fillers, colorants, lubricants (and enough hexamethylene tetramine in case of two-stage resin) are added, and the mixture is rolled on heated mixing rolls, where the reactions are carried out further, to give B-stage resin. This is nearly insoluble in organic solvents but still fusible under heat and pressure. The resin is then cooled and cut into final form. The C-stage, the final stage of infusible cross-linked polymer, is reached on subsequent fabrication, e.g. by moulding.

Procedure: Place 5 ml of glacial acetic acid and 2.5 ml of $40 \%$ formaldehyde solution in a 500 ml beaker and add 2 grams of phenol. Wrap a cloth or a towel loosely round the beaker. Pass dry HCl gas (or less preferably a few ml of conc. HCl ) into the mixture carefully. Within 5 minutes, a large mass of pink plastic is formed.

Precaution: The reaction is sometimes vigorous and it is better to be a few feet away from the beaker while adding the HCl and until the reaction is complete.

## Experiments beyond the syllabus

## Expt. No: <br> ESTIMATION OF CHROMIUM-- IODOMETRY

AIM:- To estimate the amount of chromium present in the given 100 ml of the chromium (VI) solution by Iodometry method using sodium thiosulphate solution

Chemicals required: -1) Std Potassium dichromate solution 2) Sodium thiosulphate solution
3) Potassium iodide 4) Unknown chromium (VI) solution 5) Dilute Sulphuric acid

Indicator: - Starch
Theory:-The amount of chromium present in the given unknown chromium (VI) solution can be estimated by titrating with standard sodium thiosulphate solution using starch as an indicator by Iodo metric method.

The liberated iodine can be estimated by titrating with a standard sodium thiosulphate solution usingstarch as indicator.

$$
6 \mathrm{Na}_{2} \mathrm{~S}_{2} \mathrm{O}_{3}+\mathrm{I}_{2} \longrightarrow 3 \mathrm{Na}_{2} \mathrm{~S}_{4} \mathrm{O}_{6}+6 \mathrm{NaI}
$$

Starch must be added just before the completion of the titration indicated by a faint yellow (straw) colour.

## PART A:-STANDADISATION OF SODIUM THIOSULPHATE SOLUTION

10 ml of the Standard potassium dichromate solution is pipetted out in to a clean conical flask. 10 ml . of $10 \%$ potassium iodide solution and 10 ml of dilute sulphuric acid are added to the potassium dichromate solution. The flask is covered with a watch glass for about 2-3 minutes in order to prevent the volatilisation of the liberated iodine and the solution is allowed to stand for 2-3 minutes to complete the liberation of iodine. Then, the watch-glass is removed out and then the solution is titrated against sodium thiosulphate solution present in the burette until the colour changes to pale yellow. At this stage add two ml of starch indicator and continue the titration until the colour changes from blue to green colour. It indicates the end point. The titration is repeated until two successive constant values are obtained

## PART B:-ESTIMATION OF CHROMIUM

The given unknown chromium (VI) solution present in the volumetric flask is diluted up to the mark by adding distilled water and then the solution is thoroughly mixed in order to get homogeneous solution. 10 ml of this solution is pipetted out in to a clean conical flask, 10 ml . of $10 \%$ potassium iodide solution and 10 ml of dilute sulphuric acid are added to the potassium dichromate solution. The flask is covered with a watch glass for about 2-3, minutes in order to complete the reaction.. Then, the watch-glass is removed out and then the solution titrated against sodium thiosulphate present in the burette until the colour changes to pale yellow. At this stage add two ml of starch indicator and continue the titration until the colour changes from blue to green colour. It indicates the end point. The titration is repeated until two successive constant values are obtained

## ESTIMATION OF AVAILABLE CHLORINE - IODOMETRY

AIM: - To estimate the amount of available chlorine present in the given bleaching powder sample by Iodometry method using Sodium thiosulphate solution.

Chemicals required:- 1)Bleaching powder sample 2)copper sulphate solution 3) Sodium Thiosulphate solution 4)Sulphuric acid 5) Potassium iodide.

Indicator:-Starch

Theory:- The 'Available Chlorine" refers to the chlorine liberated by the action of dilute acids on bleaching powder. The available chlorine present in the given bleaching powder is determined by titrating the acidified bleaching powder solution against standard sodium thiosulphate solution using starch as indicator by the iodometry method.

$$
\mathrm{CaCl}(\mathrm{OCl})+2 \mathrm{KI}+2 \mathrm{HCl} \longrightarrow \mathrm{CaCl}_{2}+2 \mathrm{KCl}+\mathrm{H}_{2} \mathrm{O}+\mathrm{I}_{2} \uparrow
$$

The liberated iodine, which is equivalent to the amount of available chlorine in the bleaching powder, is titrated with standard sodium thiosulphate solution using starch as indicator.

$$
2 \mathrm{Na}_{2} \mathrm{~S}_{2} \mathrm{O}_{3}+\mathrm{I}_{2} \quad \longrightarrow \quad 2 \mathrm{NaI}+\mathrm{Na}_{2} \mathrm{~S}_{4} \mathrm{O}_{6}
$$

The given sodium thiosulphate solution can be standardized with standard copper sulphate solution using starch indicator.

The given sodium thiosulphate solution can be standardized with standard copper sulphate solution using starch indicator.

$$

PART A: SANDADISATION OF SODIUM THIOSULPHATE SOLUTION
10 ml of the Standard copper solution is pipetted out in to a clean conical flask. 10 ml . of $10 \%$ potassium iodide solution are added to the copper solution. The flask is covered with a watch glass for about 2-3, minutes in order to prevent the escape of the liberated iodine and then the solution is allowed to stand for 2-3 minutes in order to complete the reaction. Then, the watch-glass is removed out and then the solution titrated against sodium thiosulphate present in the burette until the colour changes to pale yellow .At this stage add two ml of starch indicator and continue the titration until the blue colour changes from blue to green colour. It indicates the end point. The titration is repeated until two successive constant values are obtained

## PART B:-ESTIMATION OF AVAILABLE CHLORINE

10 ml of this bleaching powder suspension is pipetted out in to a clean conical flask, 10 ml of dilute HCl and 10 ml . of $10 \%$ potassium iodide solution are added to this solution. The flask is covered with a watch glass for about 2-3, minutes in order to complete the reaction. Then, the watch-glass is removed out and then the solution titrated against sodium thiosulphate present in the burette until the colour changes to pale yellow. At this stage add two ml of starch indicator and continue the titration until the blue colour disappears. It indicates the end point. The titration is repeated until two successive constant values are obtained.

## yunsingity

1. What is a Titration?
2. Define end point?
3. What is an Indicator?
4. Name the various types of Titrations.
5. What is a neutralization titration?
6. What is a redox titration?
7. What is complexometric titration?
8. What is precipitation titration?
9. What is oxidation reaction?

10 . What is reduction reaction?
11. What is an Oxidizing agent?
12. What is reducing agent?
13. What is acidimetry method?
14. What is an alkalimetry method?
15. Define permanganometry?
16. Give the colour of Phenolphthalein indicator in acidic solution.
17. Give the colour of Phenolpthalein indicator in alkali solution.
18. Give the colour of Methyl orange indicator in acidic solution.
19. Give the colour of Methyl orange indicator in alkali solution.
20. Give the indicator suitable for the estimation of sodium Hydroxide by Hydro Chloric acid.

21 Give the indicator suitable for the estimation of sodium Carbonate by Hydro Chloric acid.
22. Give the equivalent weight of Sodium Hydroxide.
23. Name the oxidizing agent \& reducing agent in the estimation of oxalic acid by $\mathrm{KMnO}_{4}$.
24. Write the redox equation in the estimation of oxalic acid by Potassium permanganate.
25. What is the indicator used in permanganometric titrations?
26. What is self indicator?
27. Why oxalic acid is heated to $60-70^{\circ} \mathrm{C}$ in the estimation of oxalic acid by Potassium permanganate.
28. What is the colour at the end point in Permangometric titrations?
29. Give the molecular weight \& equivalent weight of Oxalic acid.
30. Write the name, formula \& Molecular weight of Mohar's salt?
31. Name the oxidizing agent \& reducing agent in the estimation of Iron by Potassium permanganate.
32. Write the redox equation in the estimation of Iron by Potassium permanganate.
33. Give the role of Sulphuric acid in permanganometric titrations.
34. Name the indicator used in the estimation of Chromium by using Mohr's saltsolution.
35. Give the reasons for adding Sulphuric acid \& Phosphoric acid in the estimation of chromium by using Mohr's salt solution.
36. Give the colour changes during the estimation of Chromium by using Mohr's salt solution.
37. Why green colour is appeared at the beginning of the Dichrometric titrations.
38. Give the Molecular weight \& equivalent of Potassium Dichromate.
39. What is iodometry?
40. Give the basic principle involved in Iodometric titrations.
41. What is the indicator used in Iodometric titrations.
42. Why starch indicator is not added at the beginning of Iodometric titrations?
43. Why straw colour changes to blue with the addition of starch indicator.
44. What is the colour change at the end point of Iodometric titrations?
45. Give the differences between the estimation of Chromium by Dichromerty method and Iodometry method.
46. What is bleaching powder?
47. Give the structure of $\mathrm{CaOCl}_{2}$.
48. What is available chlorine?
49. What is E.D.T.A? Give the structure of E.D.T.A.
50. Give some examples of complexometric titrations.
51. Draw the structure of Metal - E.D.T.A. complex.
52. What is the indicator used in the estimation of Total hardness \& Zn by Complxomeric method using E.D.TA solution.
53. What is the indicator used in complexometric titations by sing E.D.TA solution?
54. Give the role of Buffer used in complexometric titations by sing E.D.TA solution.
55. Why $\mathrm{P}^{\mathrm{H}}$ of the solution should be maintained between $8-10$ in complexometric titations by using E.D.TA solution?
56. Give the colour changes taking place in complexometric titations using EBT- Indicator.
57. Give the significance of viscosity index.
58. What is $\mathrm{P}^{\mathrm{H}}$.
59. What is total alkalinity?
60. Give the possible combinations of ions causing alkalinity.
61. Give the Equivalent weight of $\mathrm{CaCO}_{3}$ ?
62. What is buffer?
63. Give the relation between Temporary hardness \& Permanent hardness.
64. Give the oxidation state of chromium in Potassium dichromate?
65. Give the effect of temperature on the dissolved oxygen content.
66. Give the difference between ferrous iron and ferric iron.
67. What is basic buffer? Give one example?
68. What is standard solution?
69. What is primary standard solution \& secondary standard solution?
70. Why $\mathrm{H}_{2} \mathrm{SO}_{4}$ is most suitable when compare with HCl and $\mathrm{HNO}_{3}$ in Permangonometric titrations.
71. What is conductometric titration?
72. What is the unit of conductance?
73. What are the factors influencing conductivity?
74. How can you identify the end point in conductometric titration?
75. What is the importance of the conductometric titration?
76. What is equivalent conductance?
77. What is effect of dilution on conductance?
78. Why ordinary water is not suitable in conductance measurement?
79. How does conductance changes when acetic acid is titrated against sodium hydroxide solution?
80. How does the conductance changes when strong acid is titrated against a strong base?
81. What are the advantages of conductometric titrations?
82. What is the effect of temperature on conductance?
83. Define electrode potential?
84. What s indicator electrode?
85. Why hydrogen electrode is not generally used in $\mathrm{P}^{\mathrm{H}}$ measurements?
86. What is the effect of temperature on $\mathrm{P}^{\mathrm{H}}$ ?
87. How the equivalence point is in acid base titrations is determined ${ }^{\mathrm{PH}}$ metrically?
88. What is the principle involved in colorimetric titrations?
89. Why do you use disodium salt of EDTA in the estimation of hardness of water?
